Outline

- Introduction
 - Inversion
 - Atmospheric scattering
- Method
 - Proxy method
 - Ratio method
 - Experiment
- Results
 - Optimized fluxes
 - Aircraft validation
- Conclusions

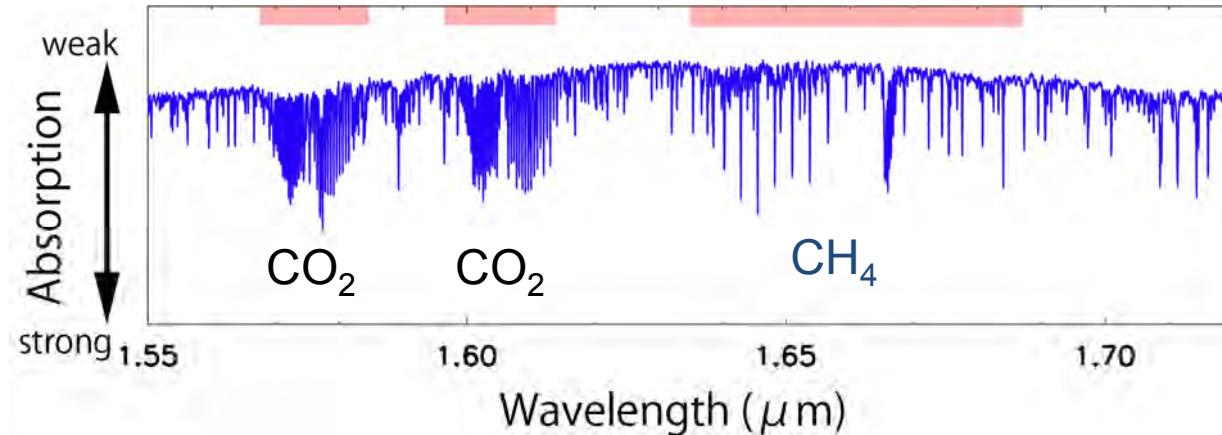

Inversion

Atmospheric Scattering

Proxy Method

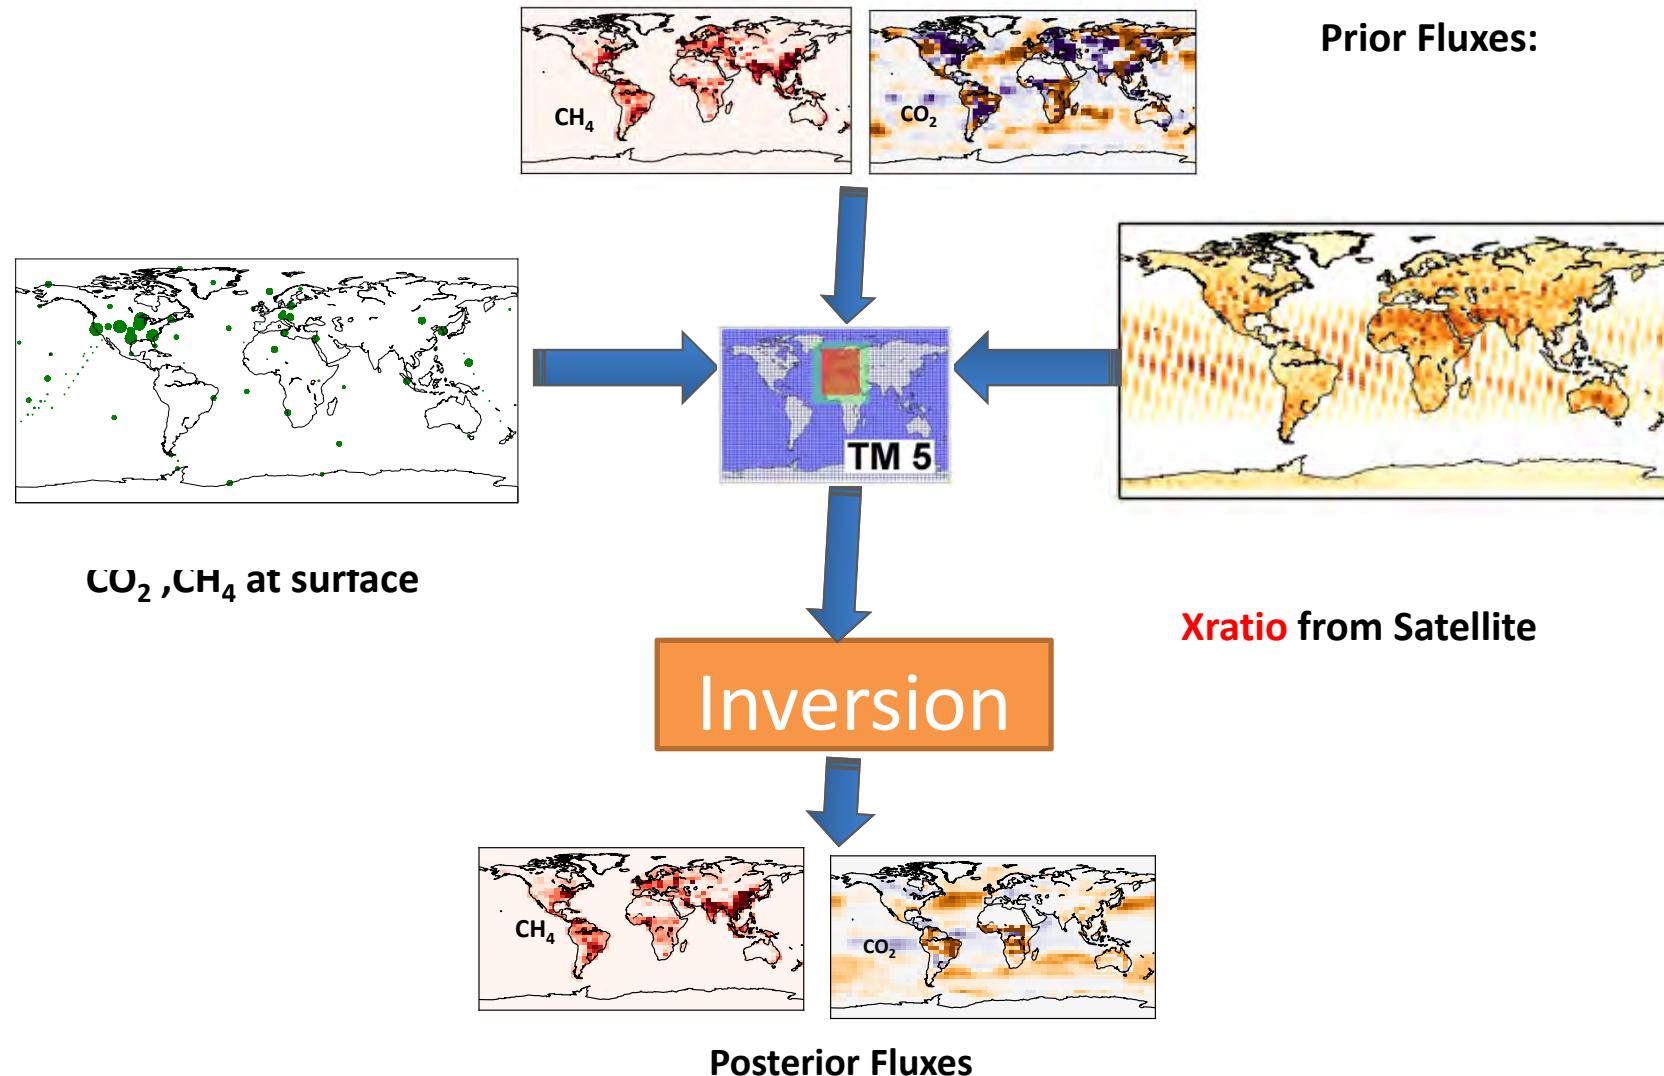

$$X_{CH4}^{proxy} = \frac{X_{CH4}^{obs}}{X_{CO2}^{obs}} \times X_{CO2}^{model}$$

Ratio Method

$$X_{ratio} = \frac{X_{CH4}^{obs}}{X_{CO2}^{obs}}$$

- The posterior fluxes of CH₄ and CO₂ are made consistent with satellite-measured Xratio in the atmosphere (Pandey et al., 2015).

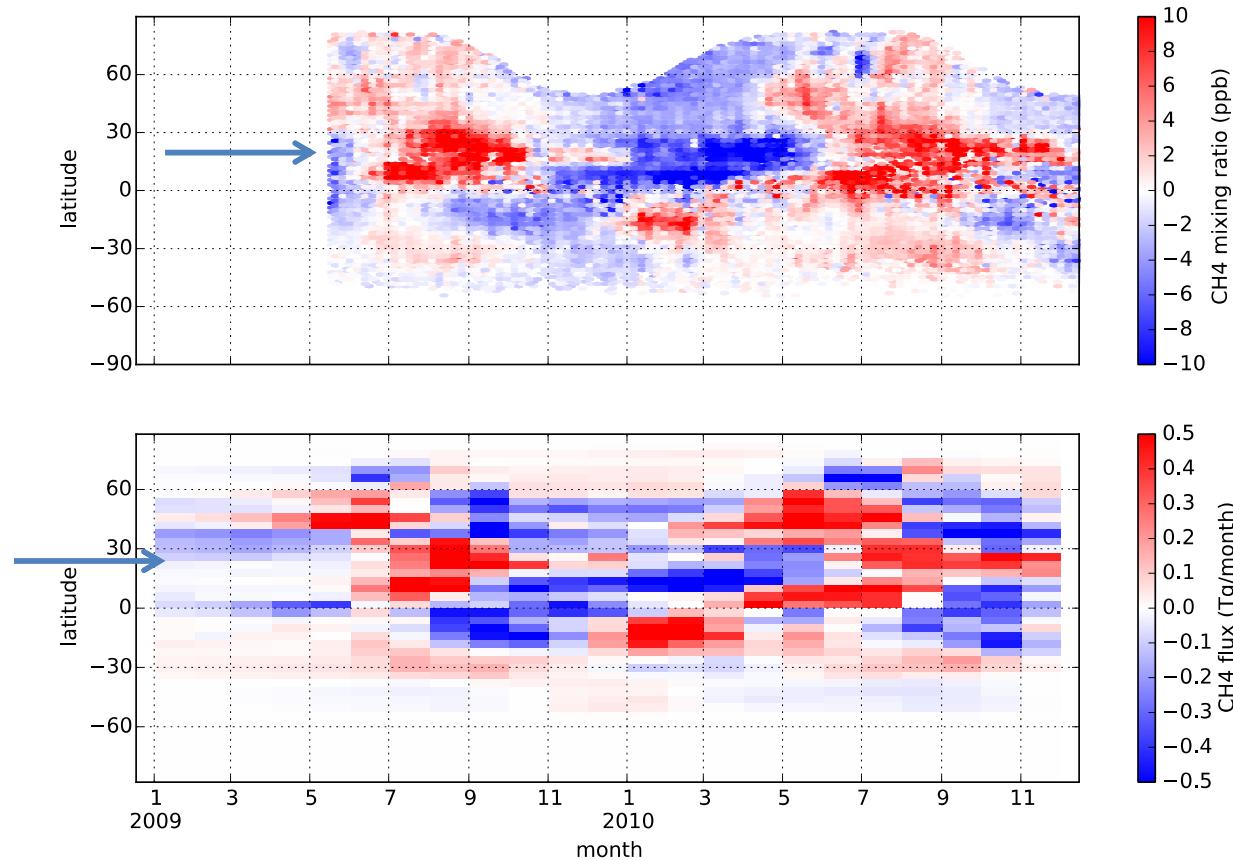

Ratio Method

Inversion Experiment

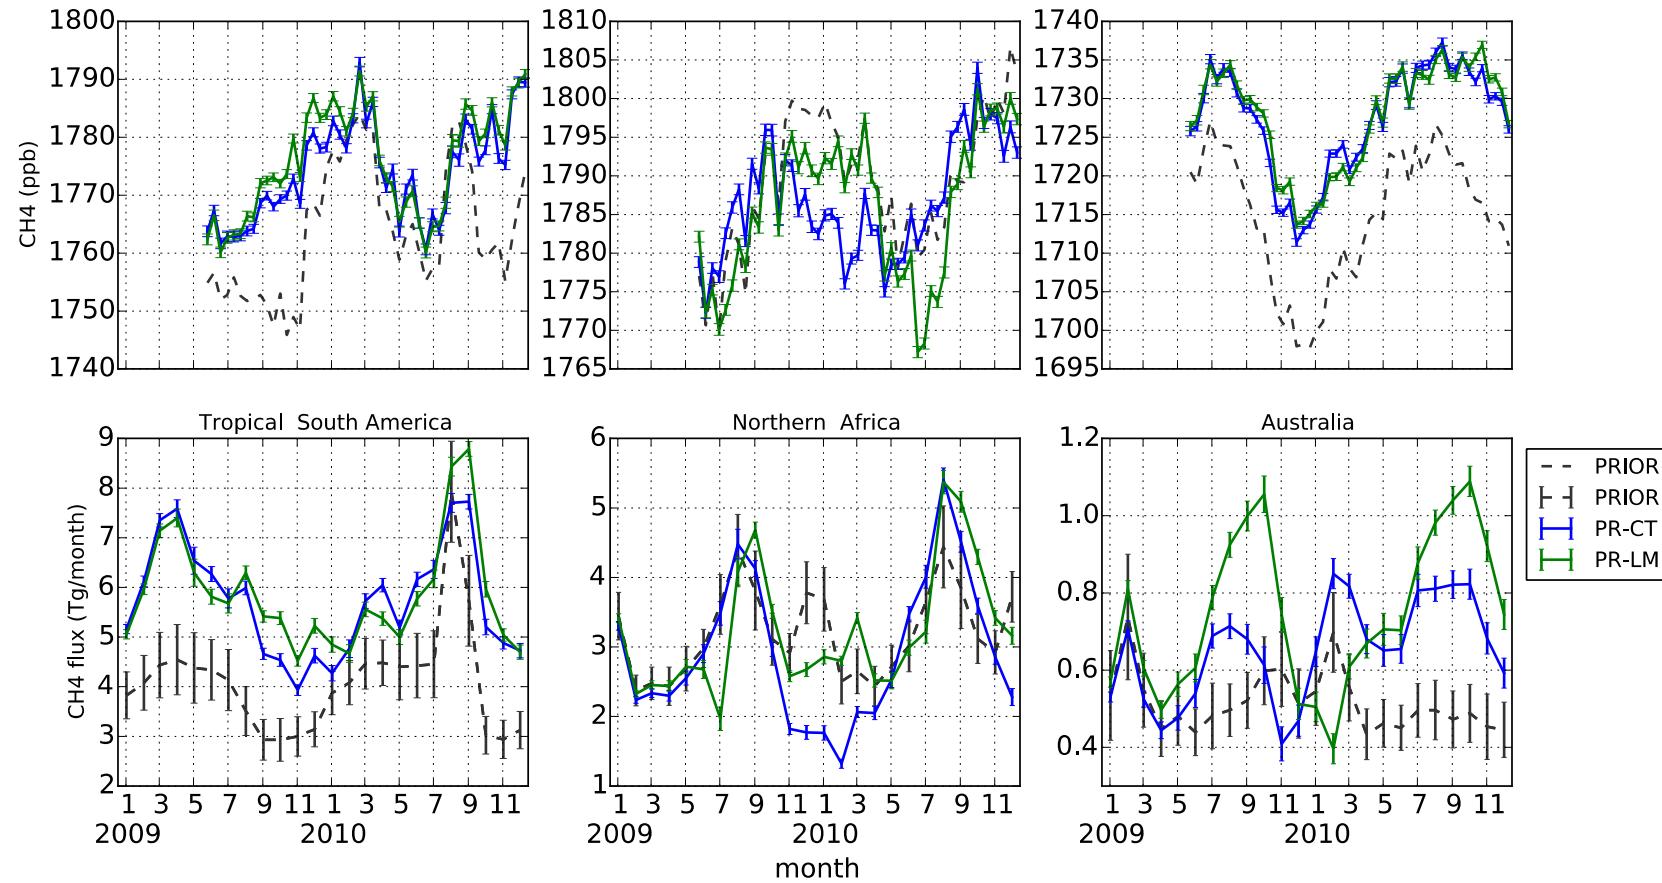

- Inversion time period: **Jan 2009 to Dec 2010**
- Surface measurements from **NOAA**
- Satellite measurements form **GOSAT**
- **TM5-4DVAR** inversion setup
- Two proxy inversions to :
 - PR-CT: model CO₂ from CarbonTracker.
 - PR-LM: model CO₂ from LMDZ.
- One ratio inversion (RATIO).

Proxy Inversion

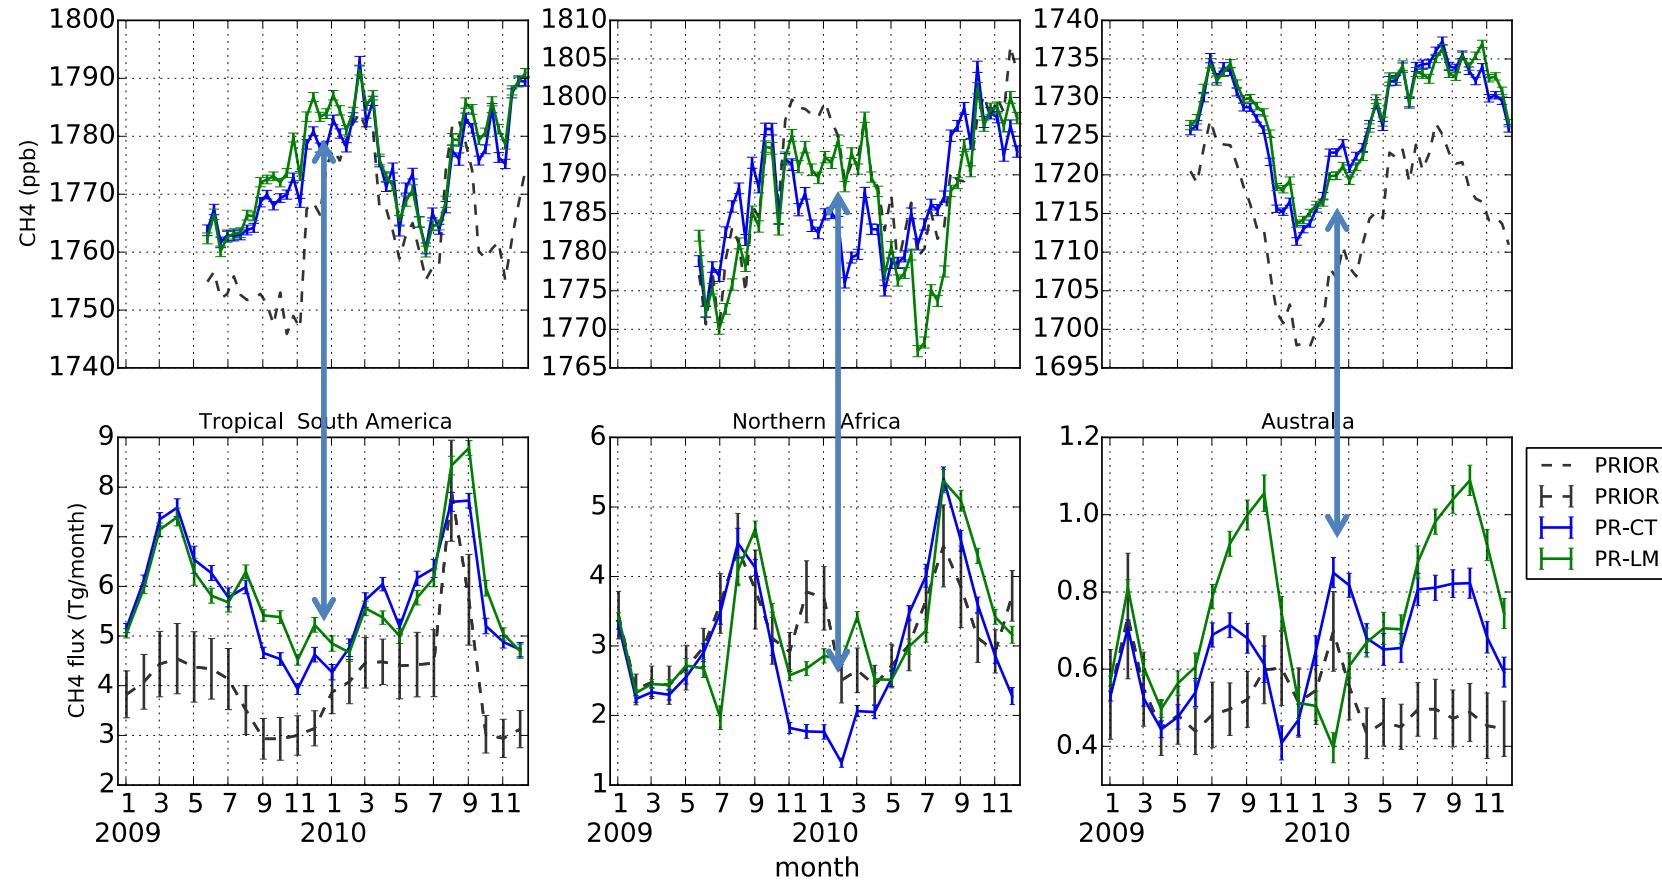

PR-CT – PR-LM

Aircraft Validation

Aircraft Validation

Conclusions

- Model derived XCO₂ has systematic biases, which propagate to proxy XCH₄.
- We find a statistically significant impact of these biases on the inverted fluxes, especially in tropical regions.
- Ratio inversion method provides an alternative, where only the satellite measured information is used.
- Validation with aircraft measurements show that the ratio method performs better than the proxy method in Tropical South America.
